

Neutrino detectors for future facilities - II

Mark Messier
Indiana University

NUFACT Summer school
Benasque, Spain June 16-18, 2008

Neutrino detectors optimized for
electron reconstruction

$\nu_{\mu} \rightarrow \nu_e$ and/or $\nu_e \rightarrow \nu_e$

Neutrino detectors optimized for $\nu_x \rightarrow \nu_e$

- I've put three basic detector technologies into this category
 - Water Cherenkov : T2K experiment
 - Totally Active Scintillator Detector ("TASD") : NOvA experiment
 - Liquid Argon Time Projection Chambers : ICARUS and future facilities
- The main focus of these experiments is electron neutrino appearance in muon neutrino beam.
- However, they can, of course, measure muons and in general have good performance for muon detection! I'll comment in the next lecture on questions about measuring the sign of the muons. The experiments listed above do not plan to run these detectors with magnetic fields and hence don't have sensitivity to the *sign* of muons.

The basic problem for $\nu_\mu \rightarrow \nu_e$ detection at a “Super Beam” facility

- In muon neutrino beams, an electron neutrino signal competes with many backgrounds
- Need large mass to get signal up
- Need fine granularity to distinguish muon neutrino and neutral-current event topologies from electron neutrino event topologies
- Need good energy resolution to home in on signal energy window

Water Cherenkov

Super-Kamiokande

Cherenkov effect

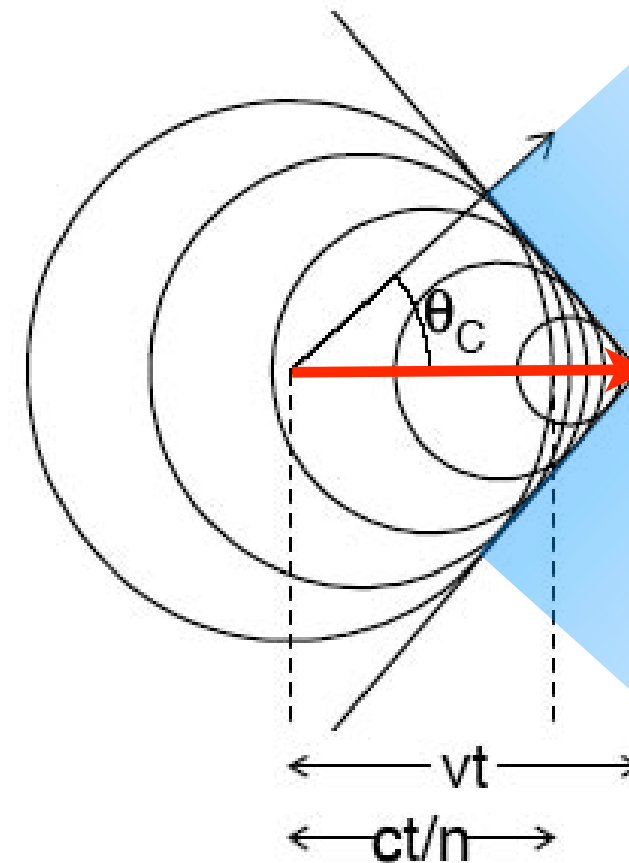

- If speed of charged particle exceeds speed of light in a dielectric medium of index of refraction n , a “shock wave” of radiation develops at a critical angle:

$$\cos \theta_C = \frac{1}{\beta n}, \beta > \frac{1}{n}$$

- Threshold for Cherenkov radiation:

$$K = m \left(\frac{n}{\sqrt{n^2 - 1}} - 1 \right)$$

- m : particle mass [GeV]
- p : particle momentum [GeV]
- E : particle total energy [GeV]
- K : particle kinetic energy [GeV]
- β : particle velocity/ c
- n : index of refraction
- θ_C : Cherenkov angle

For water,
 $n=1.33$

$\theta_C _{\beta=1.0}$	42°
$\theta_C _{\beta=0.9}$	33°
<hr/> K_{thresh} [MeV] <hr/>	
e	0.26
μ	55
τ	920
π	72
p	480

Photomultiplier tubes

Photon incident on the *photocathode* produces a *photoelectron* via the photoelectric effect. Probability to produce a photoelectron is called the *quantum efficiency* of the PMT.

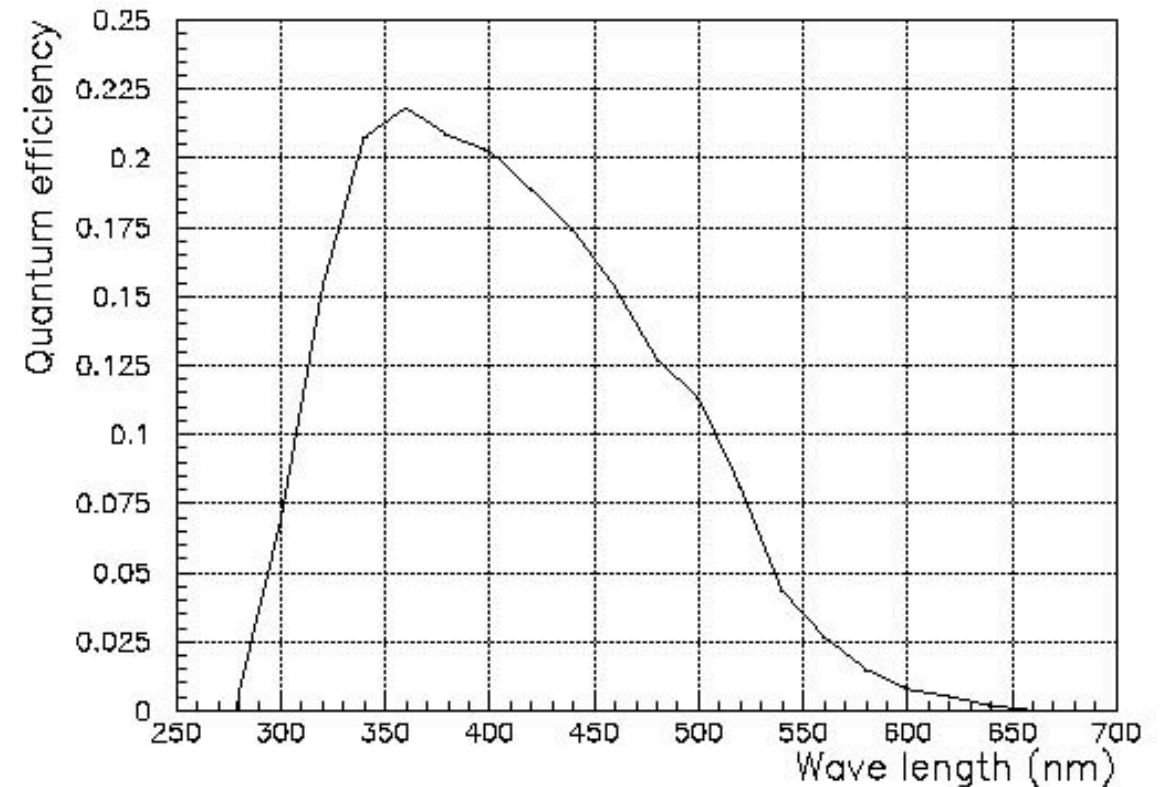

Output signal is seen as a current delivered to the *anode*. Typical *gains* are 10^6 yielding pC-scale currents

A series of plates called *dynodes* are held at high voltage by the *base* such that electrons are accelerated from one dynode to the next. At each stage the number of electrons increases. Probability to get first electron from the photocathode to the first dynode is called the *collection efficiency*.

100 ns transit time, 2.2 ns time resolution

← ● →
wavelength of Cherenkov photons in water

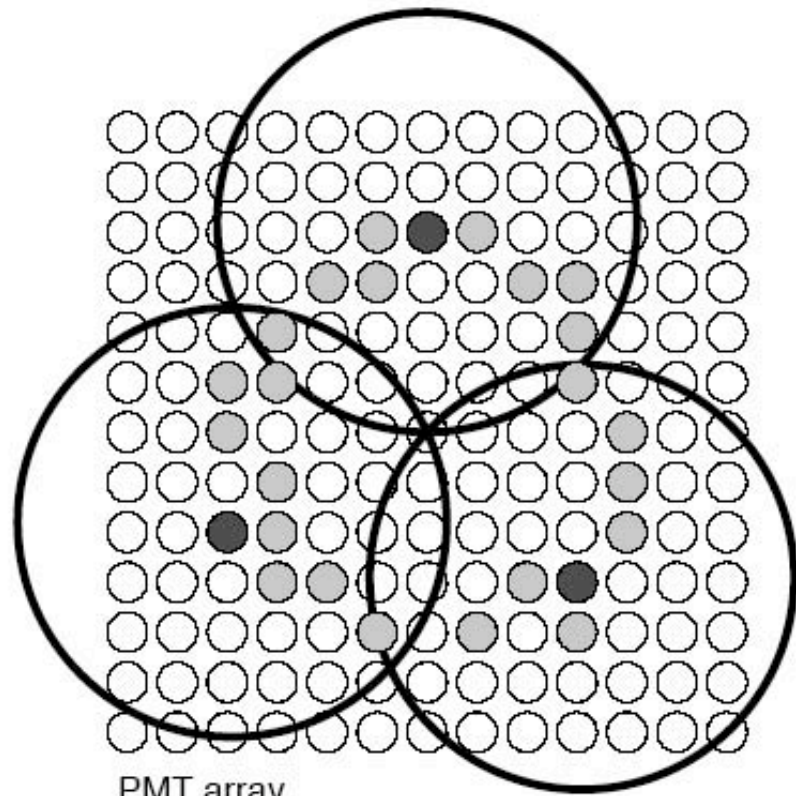

General performance

- Sensitive to a wide range of energies. Capable of electron and photo detection down to ~ 5 MeV
- Tracks produce rings on the walls. In high multiplicity events overlap of rings makes reconstruction difficult. Typically, analyses focus on quasi-elastic events which are very often single-track events.
- For single track QE events, neutrino energy reconstructed from kinematics (see next slide)

- Events with pions (and other tracks) that are below Cherenkov threshold lead to backgrounds for the quasi-elastic selection

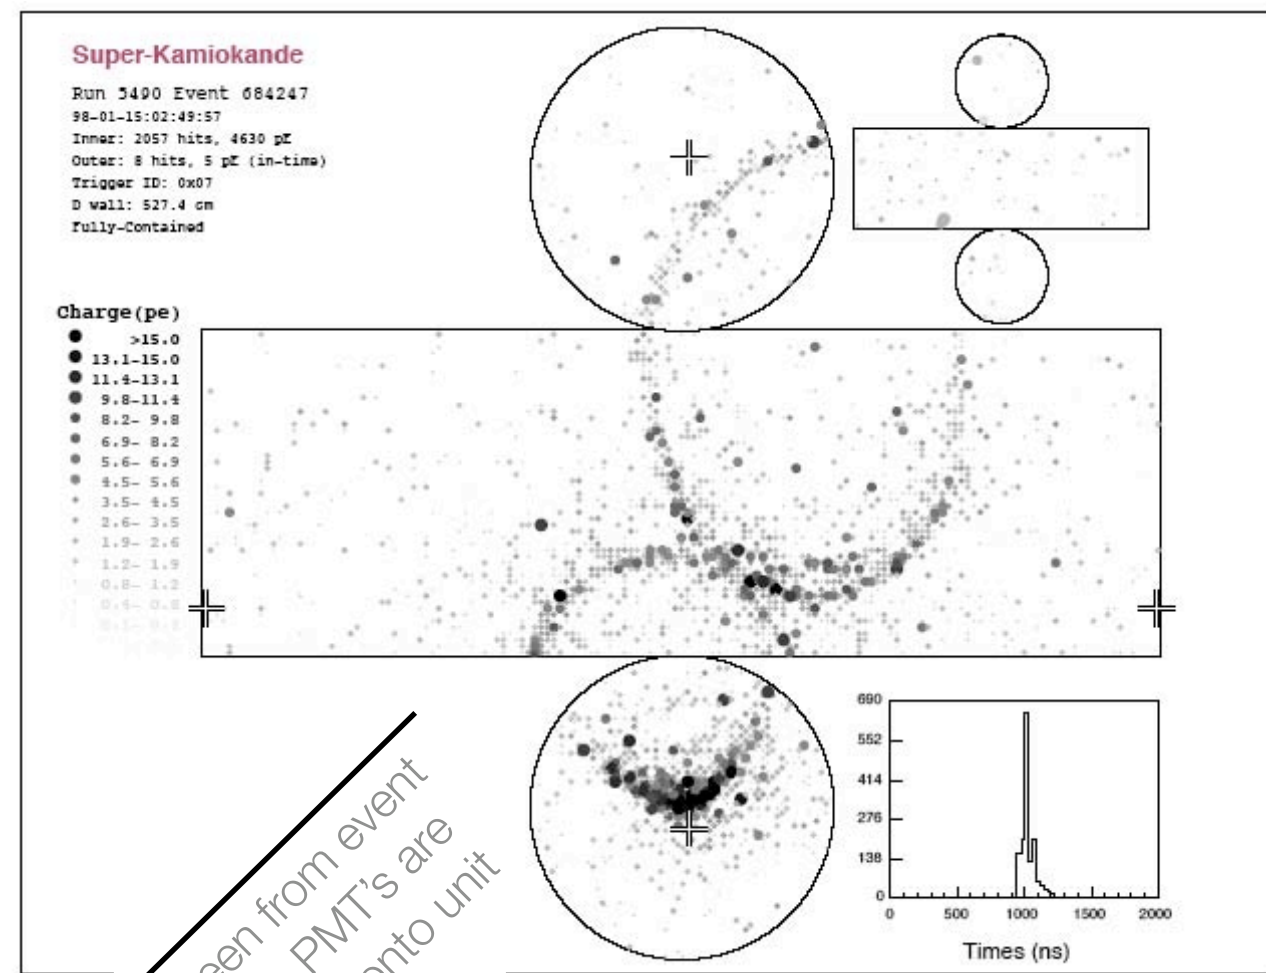

Water Cherenkov: Ring Counting

- Not-hit PMT
- Hit PMT
- PMT corresponding to circle

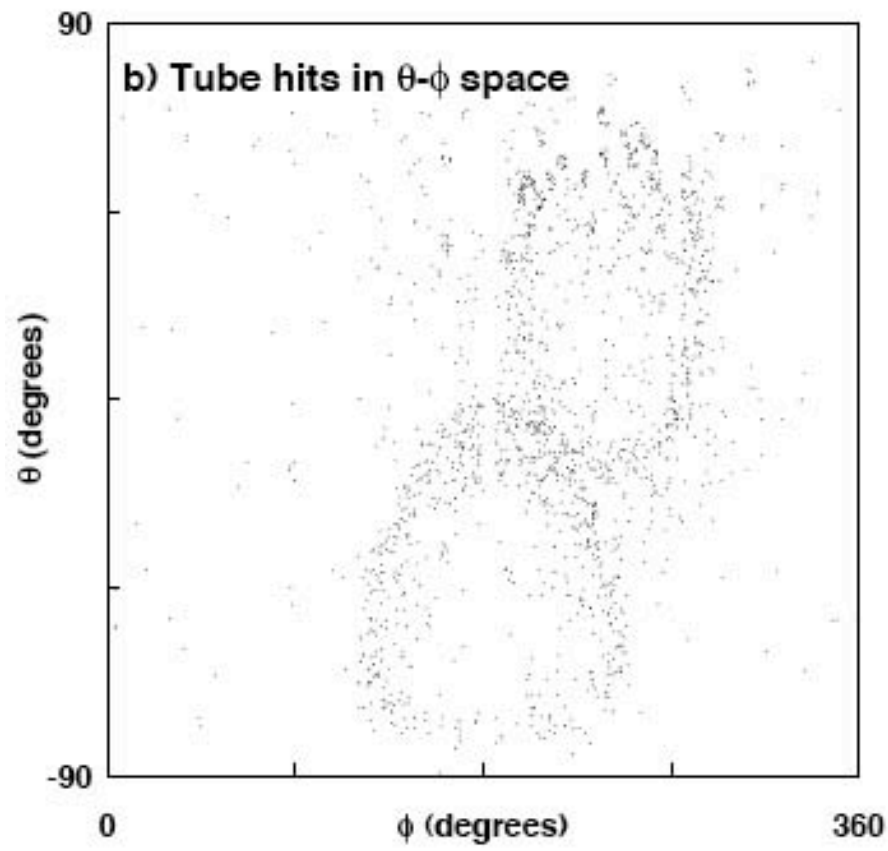

Circles overlap in center of ring corresponding to direction of particle

If you know the pattern you are looking for (line, circle, oval, etc.) the Hough transform is method for converting a pattern recognition problem to a peak finding problem

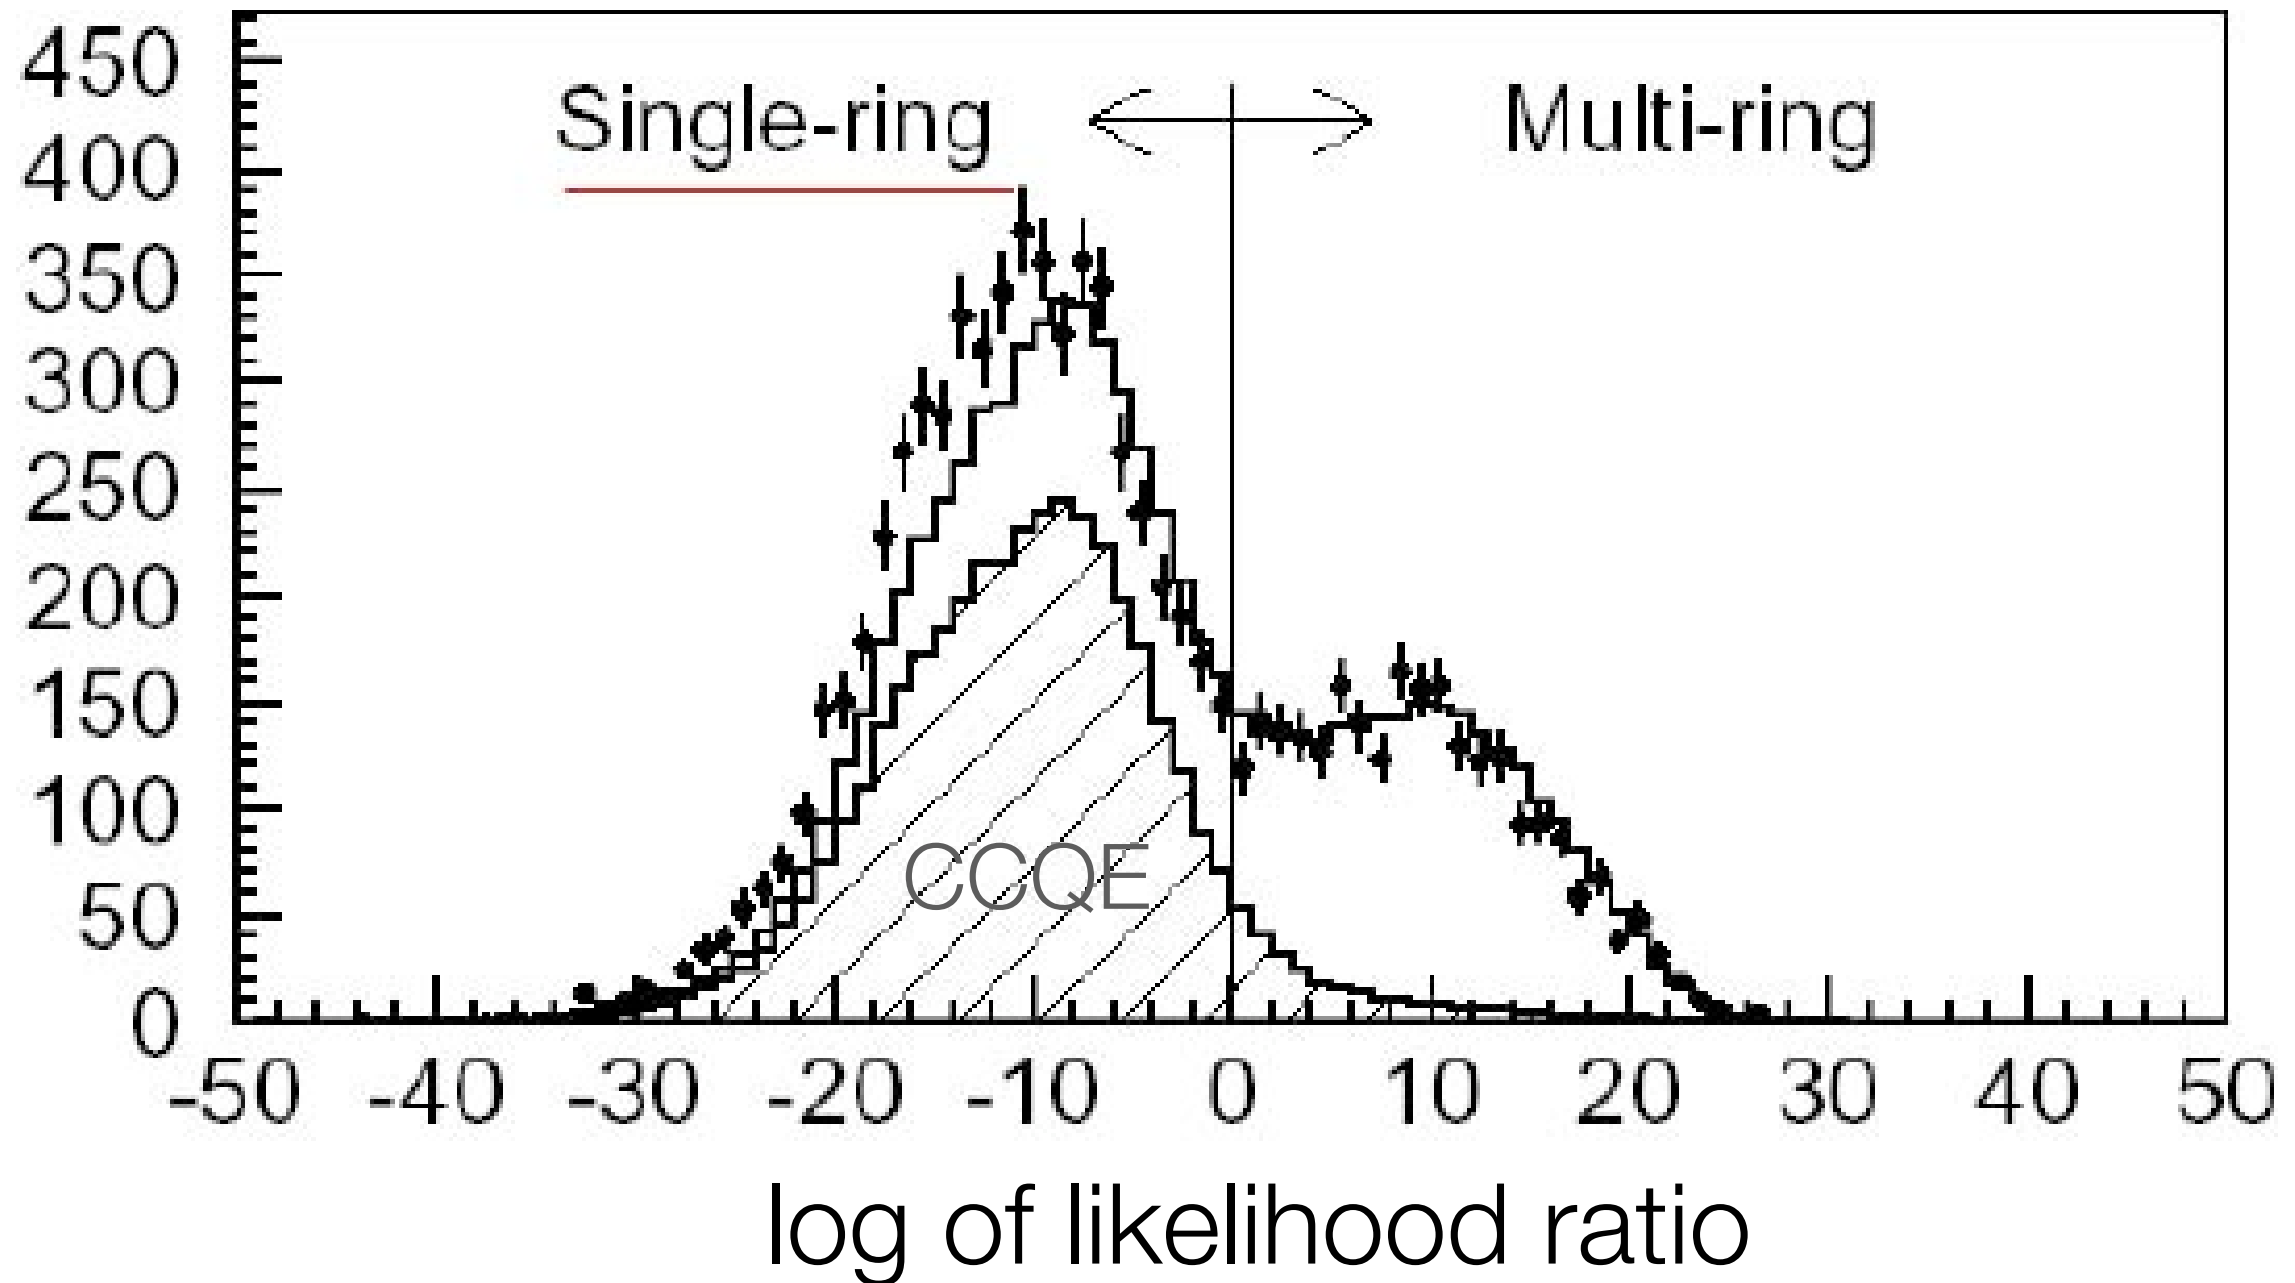

As seen from event vertex, PMT's are mapped onto unit sphere

Quasi-elastic reconstruction

$$E_\nu = \frac{m_N E_l - m_l^2/2}{m_N - E_l + p_l \cos \theta_l} \quad \textit{From 2 body kinematics}$$

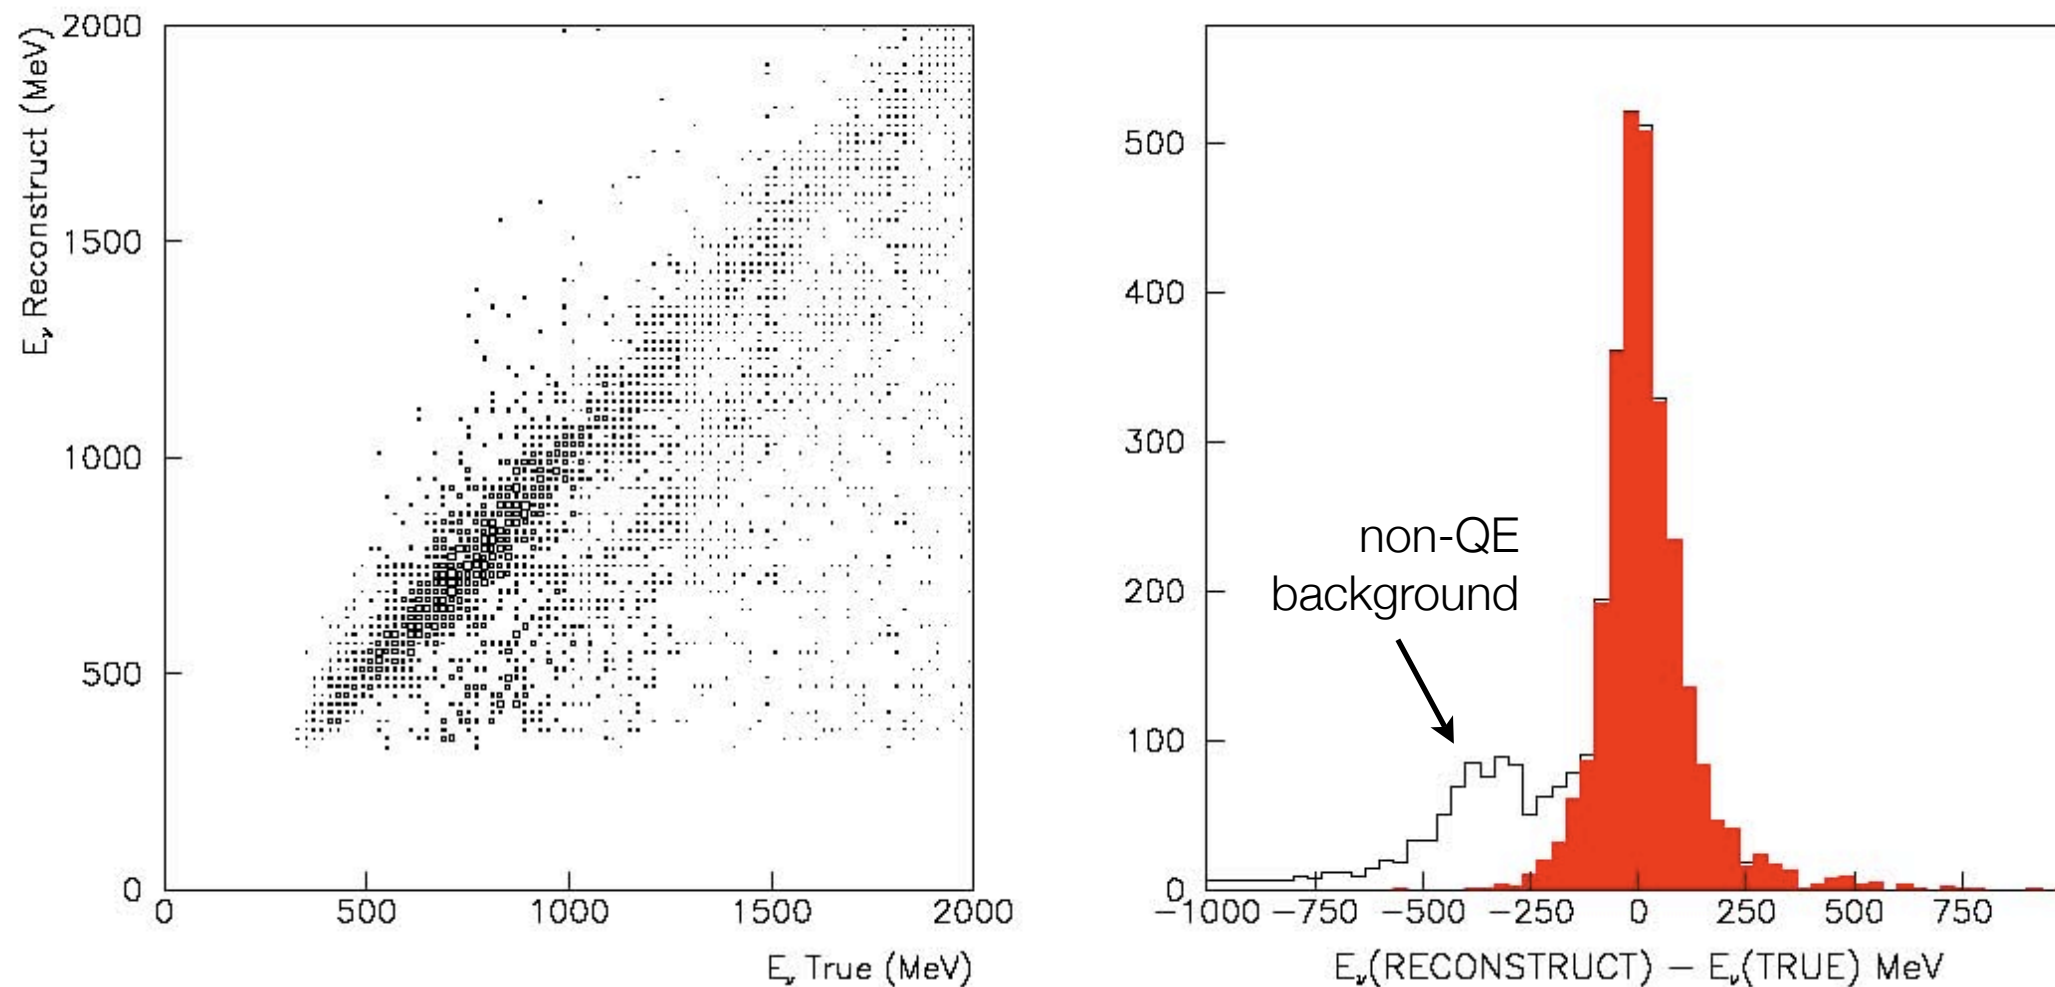

Figure 2: (left) The scatter plots of the reconstructed neutrino energy versus the true one for ν_μ events. The method of the energy reconstruction is expressed in Equation [14](#). (right) The energy resolution of ν_μ events for 2 degree off-axis beam. The shaded (red) histogram is for the true QE events.

Water Cherenkov: e/ μ identification

- At low momenta one can correlate the particle visible energy with the Cherenkov angle. Muons will have “collapsed” rings while electrons are ~always at 42°.

- At higher momenta, look at the distribution of light around Cherenkov angle. Muons are “crisp”, electron showers are “fuzzy”. See plots and figures at the right.

Totally Active Scintillator Detector ("TASD")

The NOvA Experiment

- NOvA is a second generation experiment on the NuMI beamline which is optimized for the detection of $\nu_{\mu} \rightarrow \nu_e$ and $\bar{\nu}_{\mu} \rightarrow \bar{\nu}_e$ oscillations
- NOvA is:
 - An upgrade of the NuMI beam intensity from 400 kW to 700 kW
 - A 15 kt “totally active” tracking liquid scintillator calorimeter sited 14 mrad off the NuMI beam axis at a distance of 810 km
 - A 215 ton near detector identical to the far detector sited 14 mrad off the NuMI beam axis at a distance of 1 km

Top left: extrusions coming off the line
Bottom left: testing compressive strength

Neutron scope

Los Alamos Science, Number 25 1997

Project Poltergeist, 1953

Wall reflectivity

- In NOvA cell, a photon typically bounces off the cell walls 10 times before being captured by a fiber
- This makes the reflectivity of the cell wall of crucial importance to maximizing light output:
 - ▶ $0.8^{10} = 0.11$
 - ▶ $0.9^{10} = 0.35$

10% improvement in reflectivity yields factor 3 more light!

Avalanche photo diodes (APD)

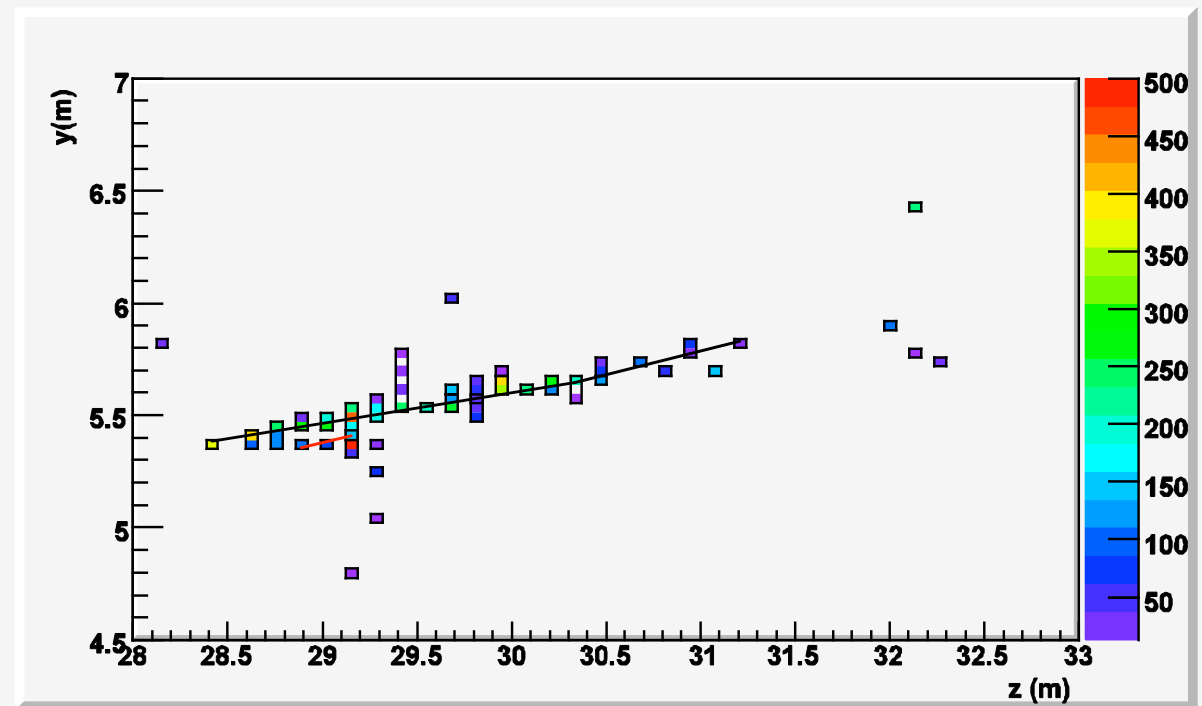

High (80%) quantum efficiency even into UV
Large dark currents - must be cooled to -15°C to get

Electron / Photon Separation

Check dE/dx at start of shower

Energy loss in the first 24mm of track: 250 MeV electrons vs. 250 MeV gammas

Some possible designs for big detectors

LArTPC: 10-50 kton storage tank. Modular drift regions.

LANDD: Single vessel designed to support vacuum

GLACIER Concept

In gas multiplication region, electrons shower in a region of high electric field. Energy/particle goes up as a result of acceleration in the field.

Path to large detectors (U.S.)

R&D issues

- Are the drift distances required by large detectors achievable in large cryostats?
- Electronic optimization. Multiplexing? Noise?
- Large wire plane construction

Tau neutrinos

- Tau neutrinos are difficult to observe
 - They are difficult to produce. First direct observation (DONUT) was via decays of charmed particles in a beam dump.
 - They are difficult to make interact: Threshold for tau production is 3.5 GeV. This puts them above the oscillation maximum for most beams designed to study oscillations at the atmospheric mass-squared scale. For example, for $L=735$ km, $E_{\text{max}} = 1.5$ GeV, which is below threshold
 - They are difficult to detect: The lifetime of the tau is 291 fs; Even when highly boosted, decay length is only a few mm. Required a very finely segmented vertex region
- Tau neutrinos produce backgrounds to electron neutrino searches:

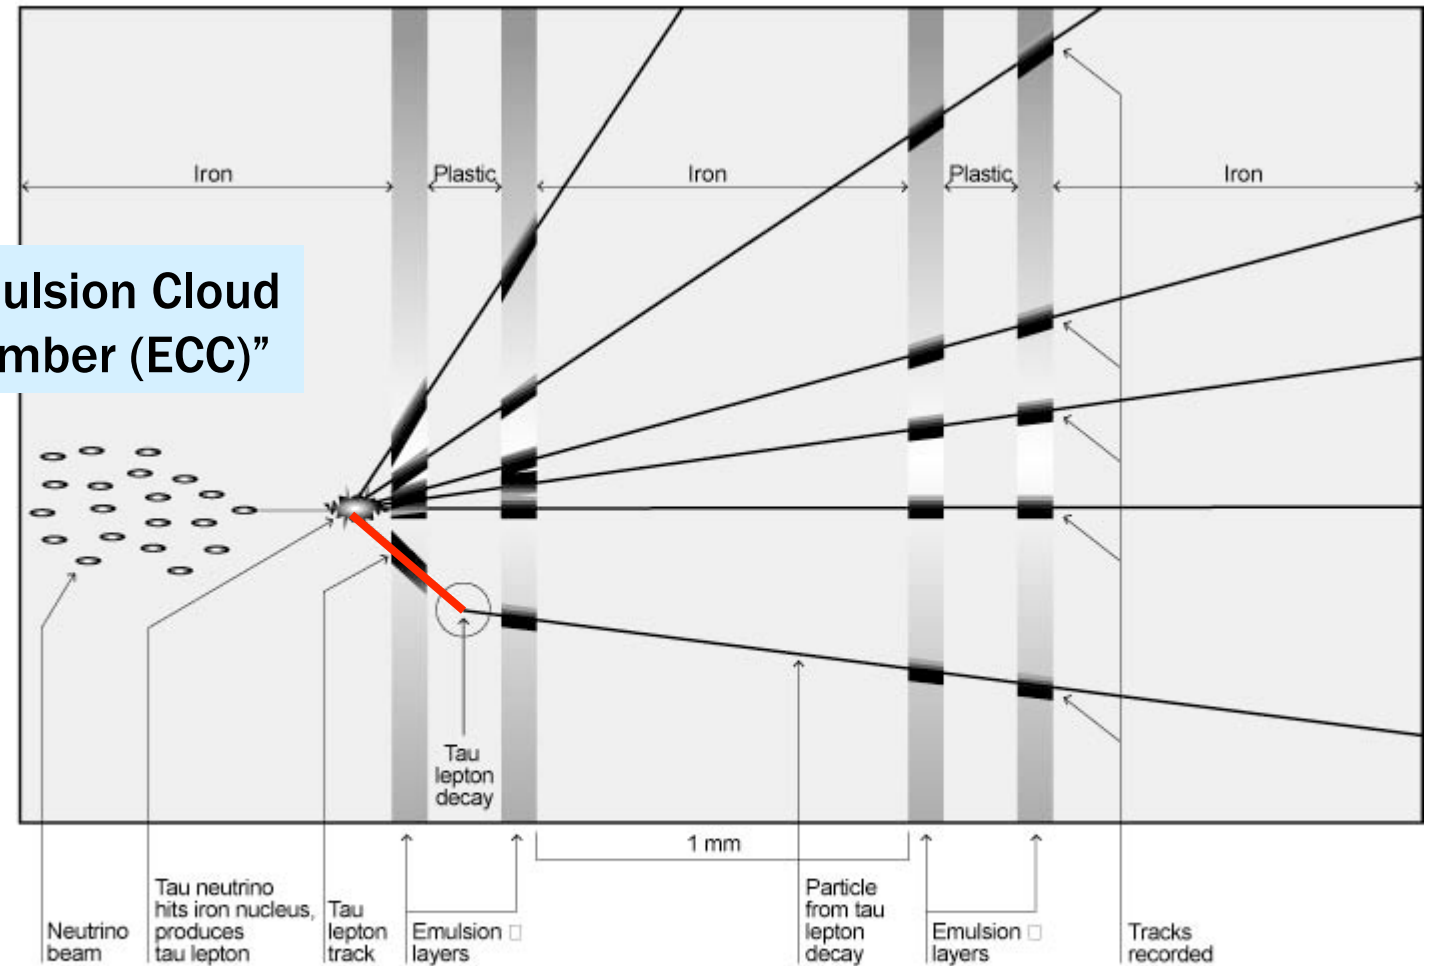

$$\tau \rightarrow e \nu_e \nu_\tau$$

Tau Neutrino Detection

- Several experiments look for tau neutrinos
- Observed by DONUT experiment
- Sought from oscillations by CHORUS and OPERA
- All of the above experiments have used thin films of photographic emulsions placed between target layers
- Use of emulsion allows for resolution of short tau track and search for its decay either through a track kink or to multi-prongs
- Emulsion target followed by other detectors which provide tracking and tell you where you had a neutrino interaction and which emulsions you should develop

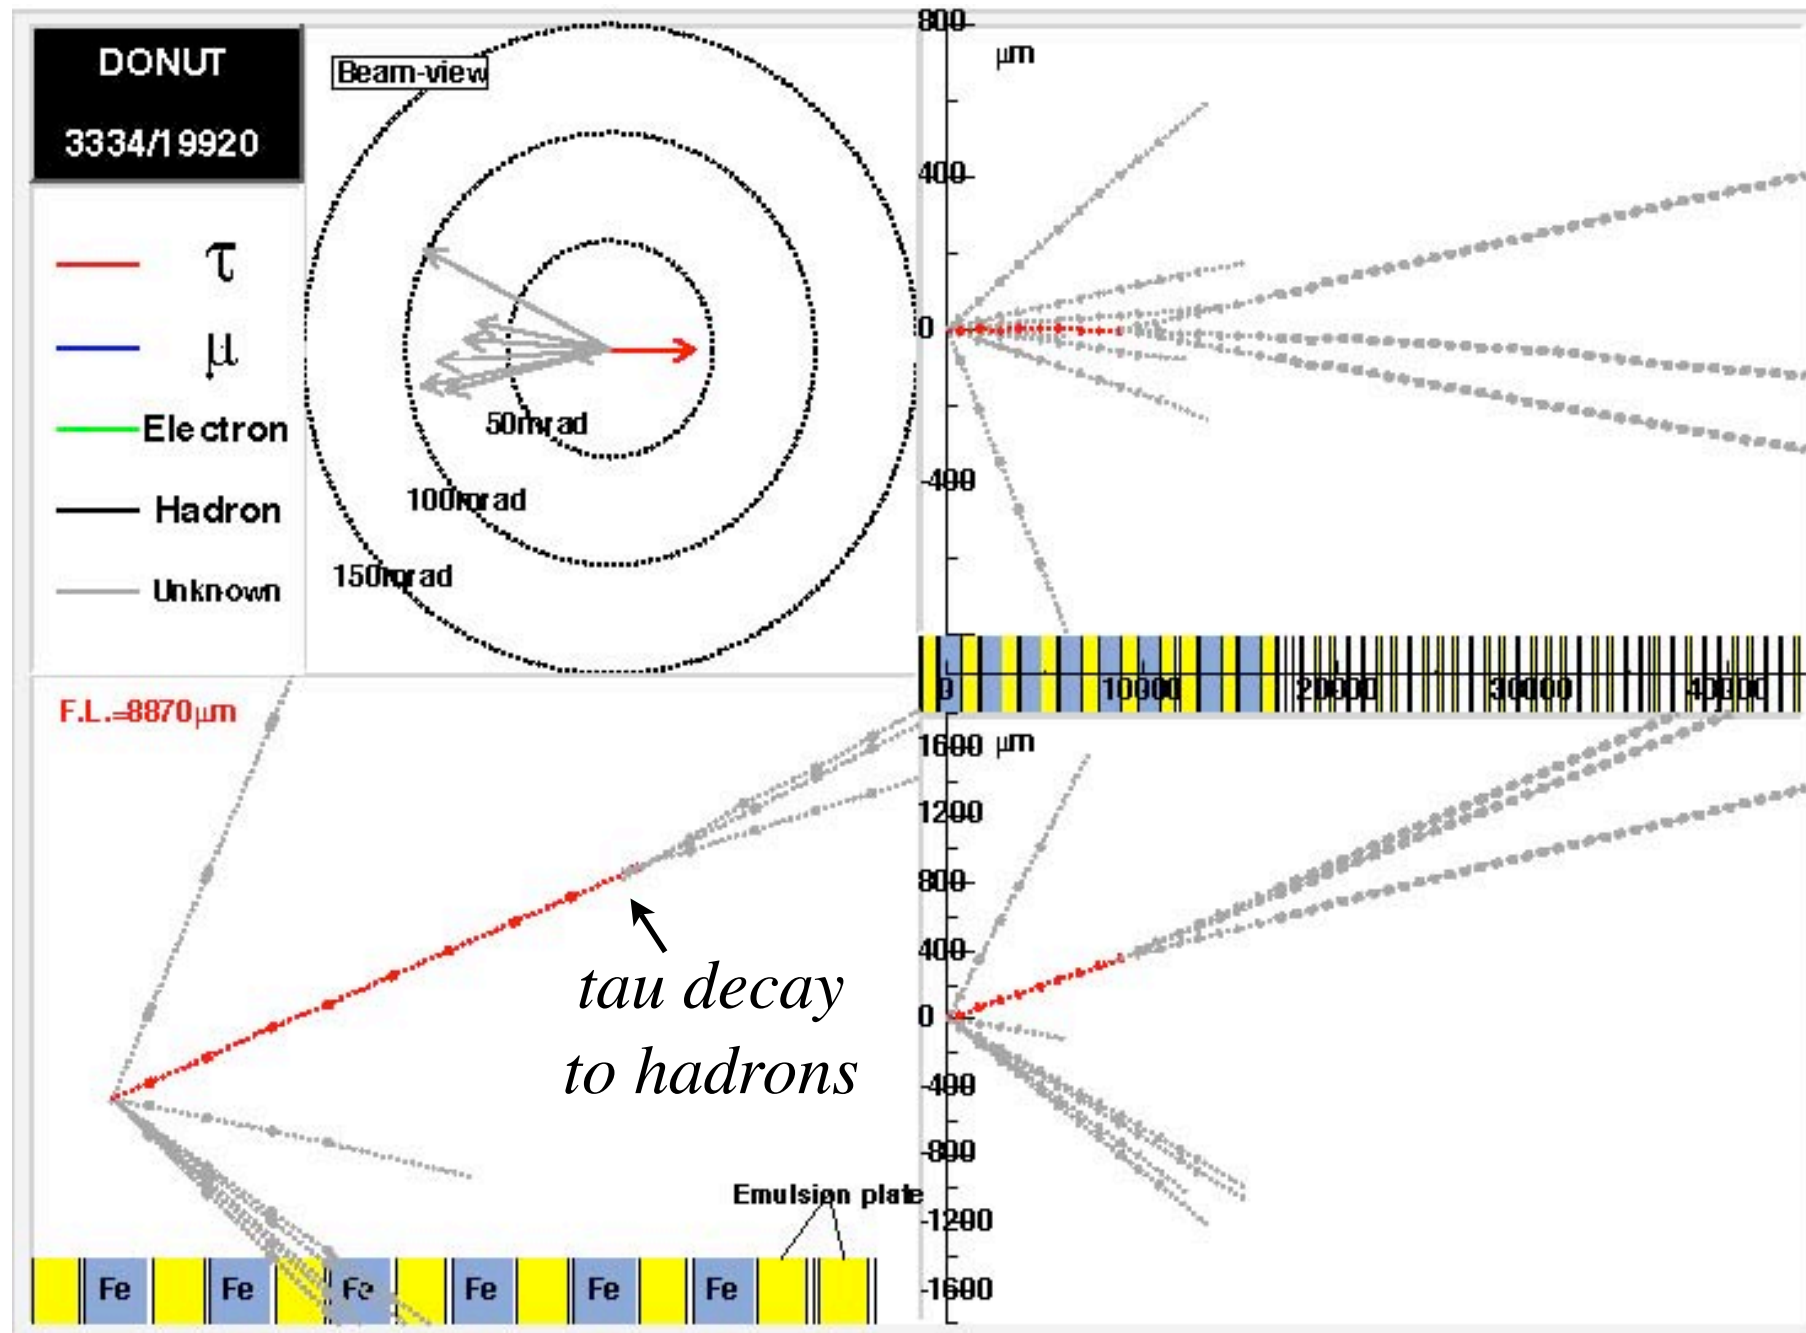

Detecting a Tau Neutrino

“Emulsion Cloud Chamber (ECC)”

Of one million million tau neutrinos crossing the DONUT detector, scientists expect about one to interact with an iron nucleus.

Tau Neutrino Detection by DONUT Collaboration

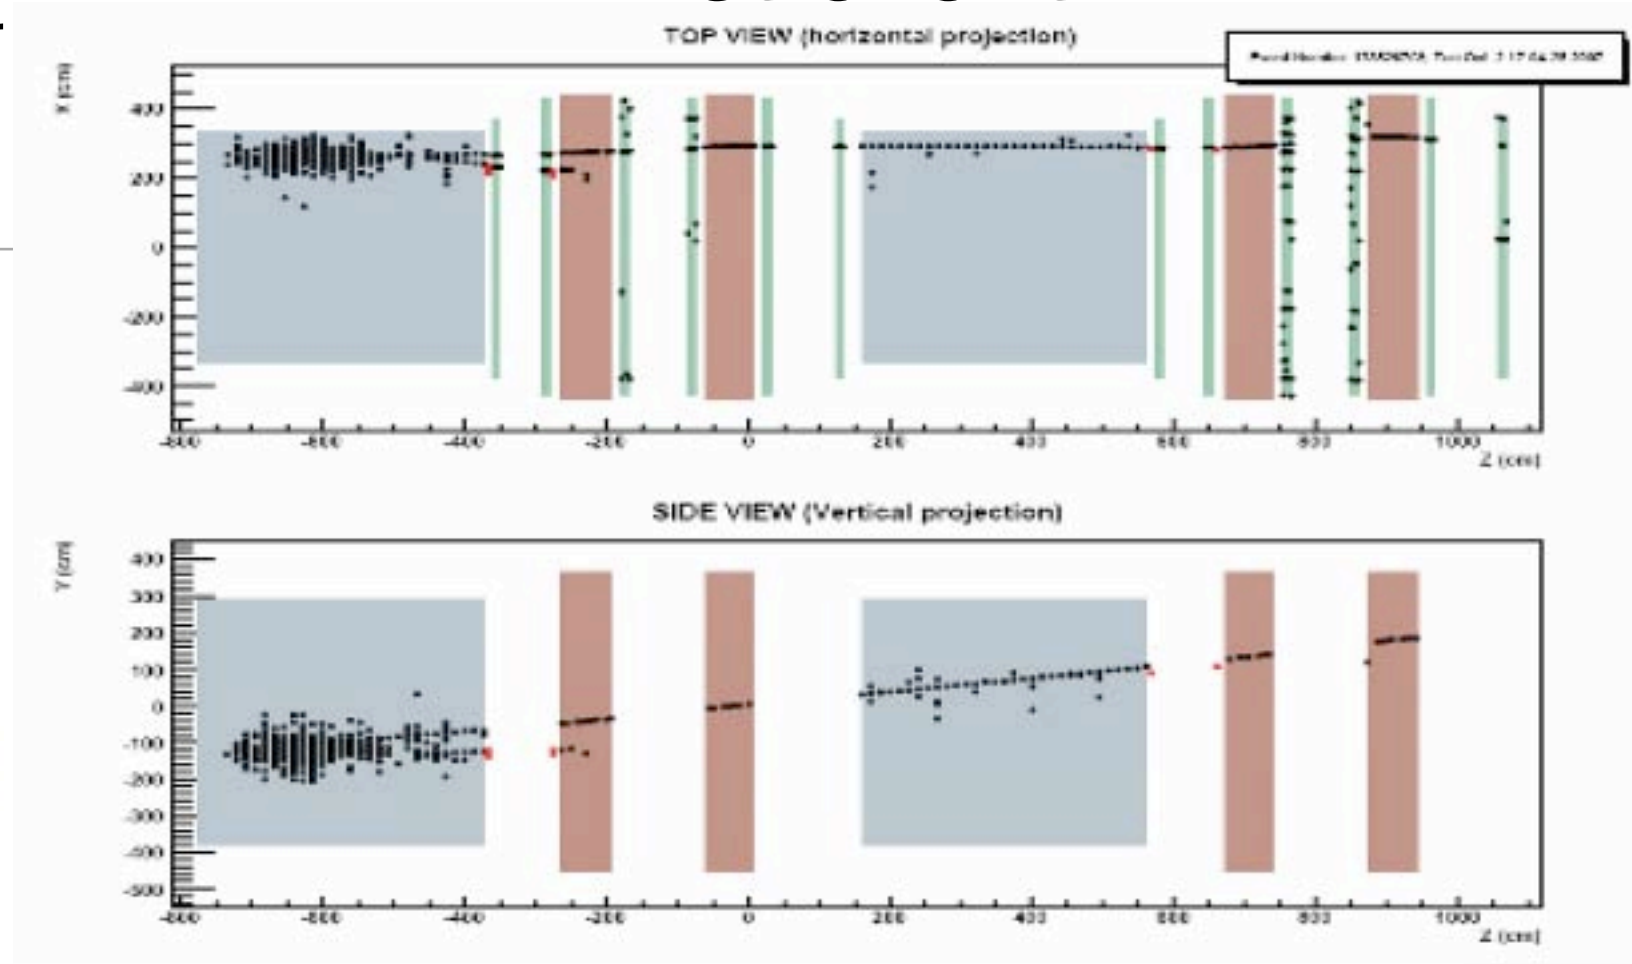

OPERA Experiment In CNGS beam

OPERA uses bricks of lead/
emulsion embedded in a solid
scintillator-based tracking

While large detectors may not be able to identify tau neutrino events one-by-one, they may be able to separate tau neutrino events from other events statistically
