Analogues: Intuitive picture

- Light cannot escape from black hole=Sound cannot travel upstream in supersonic flow
- Subsonic/supersonic flows = Exterior/interior black hole
- Subsonic-supersonic interface = Event horizon

BEC analogues: Andreev-Hawking effect

- Bogoliubov approximation for atomic condensates:

- Homogeneous condensate flow:

$$\Psi_0(x) = \sqrt{n_0} e^{iqx}$$

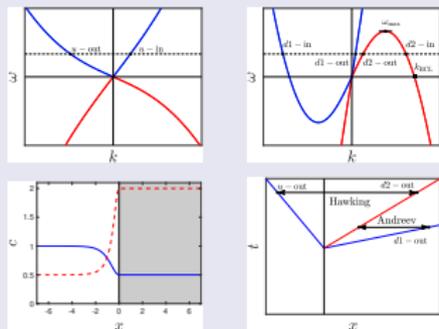

- Bogoliubov dispersion relation:

$$(\omega - vk)^2 = c^2 k^2 + \frac{\hbar^2 k^4}{4m^2} = c^2 k^2 \left(1 + \frac{(k\xi)^2}{4} \right)$$

$$c = \sqrt{gn_0/m}, \quad v = \frac{\hbar q}{m}, \quad \xi = \frac{\hbar}{mc}$$

- Black-hole GP solution: Subsonic/Supersonic Interface

- \nexists global vacuum \rightarrow Spontaneous, correlated quasiparticle emission \rightarrow Andreev-Hawking effect \rightarrow No need for metrics!

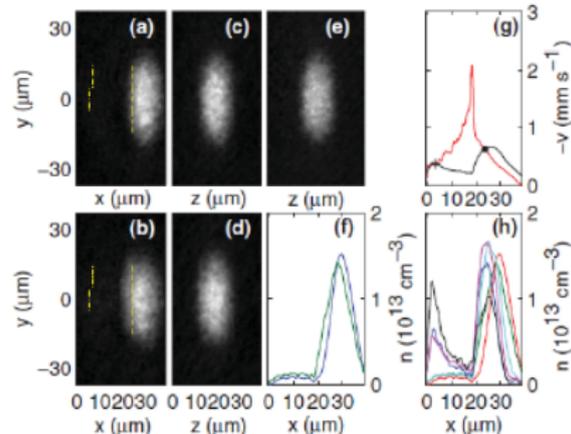

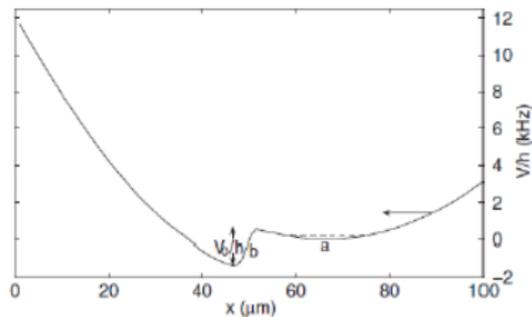

I. Zapata, F. Sols, PRL 102, 180405 (2009); A. Recati et al., PRA 80, 043603 (2009); JRMdN et al., Comptes Rendus Physique 25, S2 (2024)

Realization of a Sonic Black Hole Analog in a Bose-Einstein Condensate

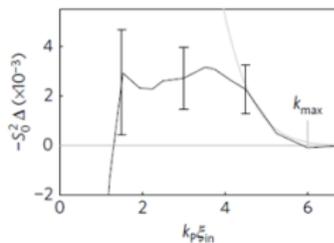

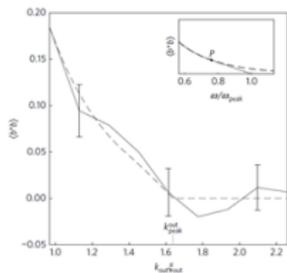

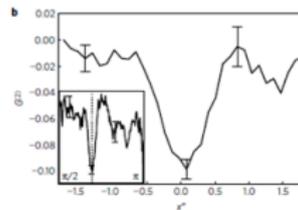

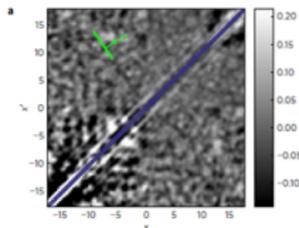

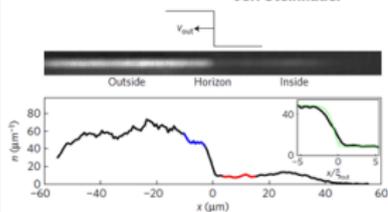

Oren Lahav, Amir Itah, Alex Blumkin, Carmit Gordon, Shahar Rinott, Alona Zayatz, and Jeff Steinhauer

Technion—Israel Institute of Technology, Haifa, Israel

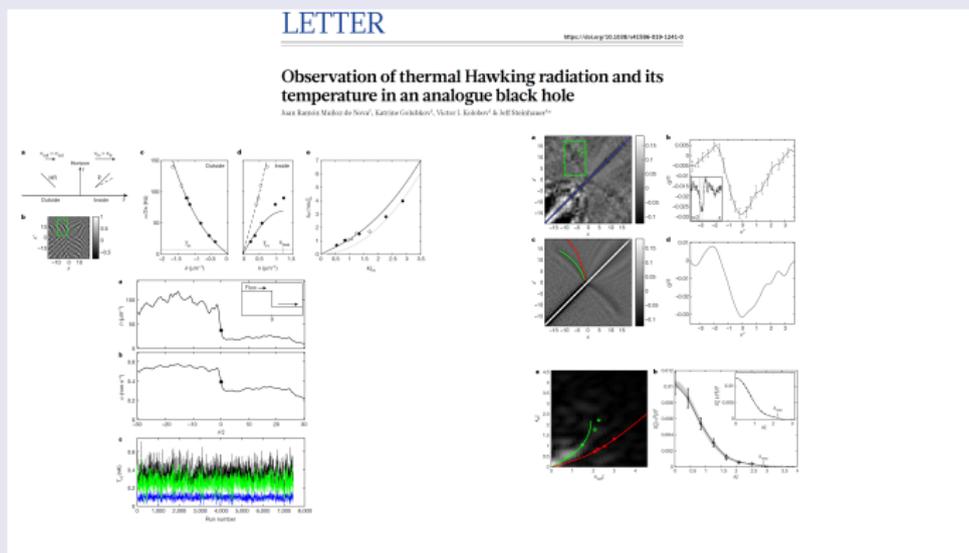

Observation of quantum Hawking radiation and its entanglement in an analogue black hole

Jeff Steinhauer

BEC (Experiment): 2019 Observation+Hawking Temperature

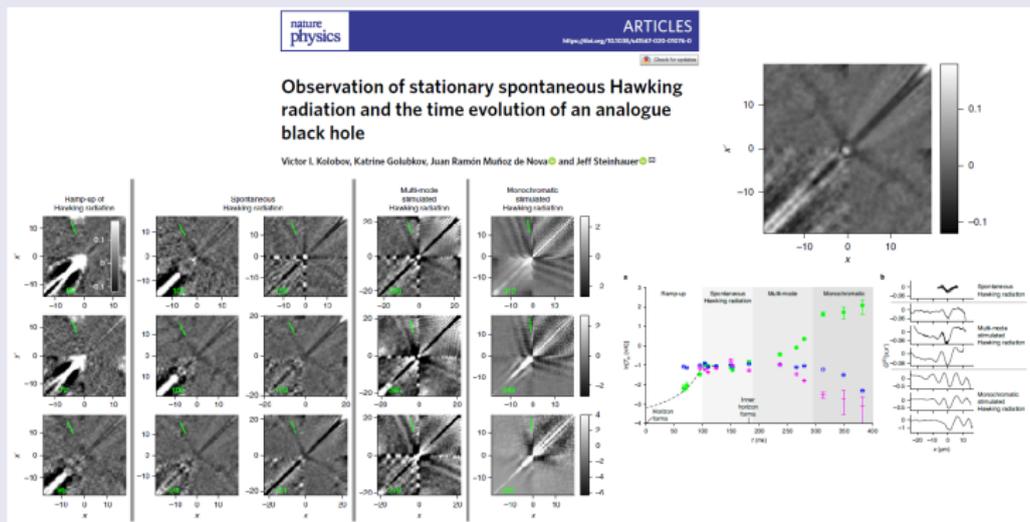

- 2016 experimental data did not quantitatively fit theory \rightarrow *Thin-moustache mystery!*

JRMdN, K. Golubkov, V. I. Kolobov, J. Steinhauer, *Nature* 569, 688 (2019)

BEC (Experiment): 2021 Observation Stationarity + Life of Black Hole

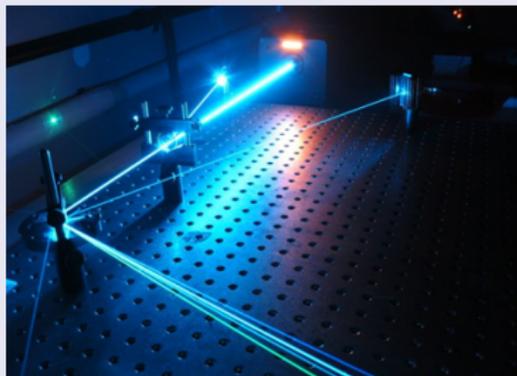

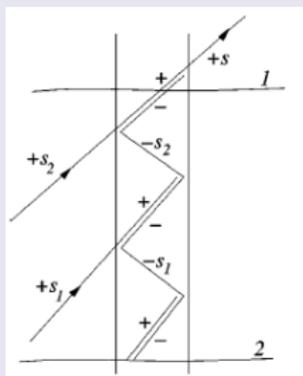

- Experiment extended (97000 repetitions over 124 days!) to observe life of analogue black hole and birth of inner horizon.

V. I. Kolobov, K. Golubkov, **JRMdN**, J. Steinhauer, *Nature Physics* 17, 362 (2021)

Black-hole laser

- Pair of horizons: Hawking radiation bounces back and forth \rightarrow Self-stimulation \rightarrow Dynamical instability (Complex BdG modes)
- Hawking radiation must be able to travel back from inner horizon \rightarrow Superluminal dispersion relation $\omega^2 = c^2 k^2 \left(1 + \frac{k^2}{\Lambda^2}\right)$
- BEC quasiparticles are superluminal! \rightarrow Planck scale $\Lambda \leftrightarrow$ Healing length ξ

S. Corley and T. Jacobson PRD 59, 124011 (1999).

Degenerate BHL: Degenerate parametric amplifier

- Lasing cavity with single degenerate mode $\Omega = i\Gamma = -\Omega^*$:

$$M_{0z_I} = \Omega z_I, \quad M_{0z_S} = \Omega^* z_S, \quad (z_I|z_I) = (z_S|z_S) = 0.$$

- Convention: $(z_I|z_S) = i$, $\bar{z}_{I,S} = z_{I,S} \rightarrow$ Properly normalized mode:

$$Z = \frac{z_I - iz_S}{\sqrt{2}} \implies \hat{a} = (Z|\hat{\Phi}) = \frac{\hat{X} + i\hat{P}}{\sqrt{2}}$$

- BHL dynamics: *Degenerate* parametric amplifier

$$\hat{K} = \hat{K} - \mu\hat{N} \simeq i\Gamma \frac{(\hat{a}^\dagger)^2 - \hat{a}^2}{2} = \Gamma \frac{\hat{X}\hat{P} + \hat{P}\hat{X}}{2}$$

- Lasing amplitude=Position operator \hat{X} in DPA:

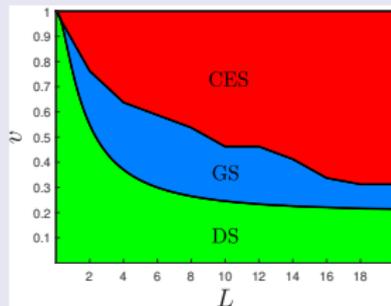

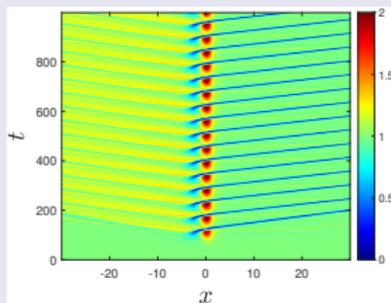

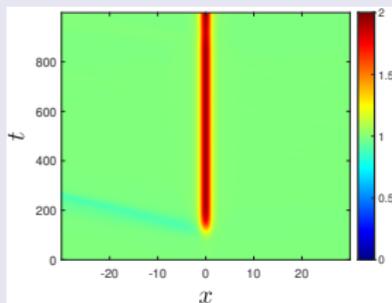

$$\hat{\Phi}(x, t) \simeq \hat{X}z_I(x)e^{\Gamma t} + \hat{P}z_S(x)e^{-\Gamma t}$$

- Time evolution $U(t) = e^{-i\hat{K}t}$:

$$U(t)|X\rangle = e^{\frac{\Gamma t}{2}} |Xe^{\Gamma t}\rangle, \quad \hat{X}(t) = U^\dagger(t)\hat{X}U(t) = e^{\Gamma t}\hat{X}$$

BHL Phase Diagram

- Linear instability exponentially amplified until... What is the final fate of a BHL?
- Universal mean-field dynamical phase diagram: Ground state vs. periodic continuous emission of solitons (CES) state.
- GS/CES transition above critical velocity $v > v_c \rightarrow$ Nonlinear Landau criterion for superfluidity!

JRMdN, *S. Finazzi, I. Carusotto, PRA 94, 043616 (2016)*

JRMdN, *P. F. Palacios, I. Carusotto, F. Sols, NJP 23, 023040 (2021)*

Spontaneous Floquet states

- CES state: simplest realization of spontaneous Floquet state
- Spontaneous Floquet state: Floquet state from time-independent Hamiltonian due to interactions
- Condensates: Self-consistent Floquet solutions to GP equation $\Psi(x, t) = e^{-i\mu t}\Psi_0(x, t)$, $\Psi_0(x, t + T) = \Psi_0(x, t)$:

$$[i\hbar\partial_t - \mu]\Psi_0(x, t) = H_{GP}(t)\Psi_0(x, t)$$

$$H_{GP}(t) = \left[-\frac{\hbar^2}{2m}\nabla^2 + V(\mathbf{x}) + g|\Psi_0(\mathbf{x}, t)|^2 \right] = H_{GP}(t + T)$$

- Feasible in a number of variational many-body ansätze: MCTDH method, Hartree-Fock, Gutzwiller ansatz...

JRMdN, *F. Sols*, *PRA* 105, 043302 (2022)

Spontaneous Floquet states

- Intriguing features:

- Temporal Floquet-Nambu-Goldstone mode with zero quasi-frequency in the Bogoliubov-Floquet spectrum
- Energy conservation \rightarrow Conserved Floquet charge $F \rightarrow$ Spontaneous Floquet states are “isofloquetic” (\sim “isochoric”)

$$dE = \omega dF + \sum_i \lambda^i dQ_i$$

- Driven Floquet states are “isoperiodic” (\sim “isobaric”) \rightarrow Floquet enthalpy:

$$I = E - \omega F \rightarrow dI = -F d\omega + \sum_i \lambda^i dQ_i$$

- Quantum amplitude of temporal FNG \rightarrow Tangible realization of Time Operator in Quantum Mechanics!

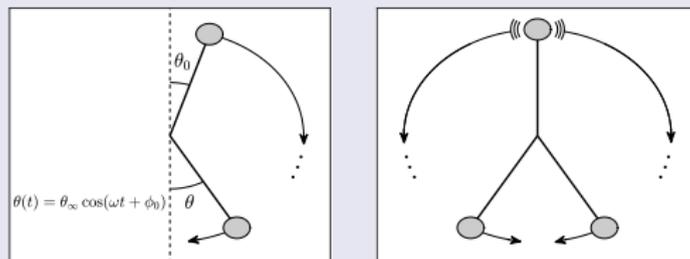

JRMdN, *F. Sols*, *Quantum* 9, 1850 (2025)

Quantum-Classical BHL

- So far, only mean-field spontaneous Floquet state \rightarrow Fixed oscillation phase $\phi_0 \rightarrow$ Not truly spontaneous symmetry breaking!

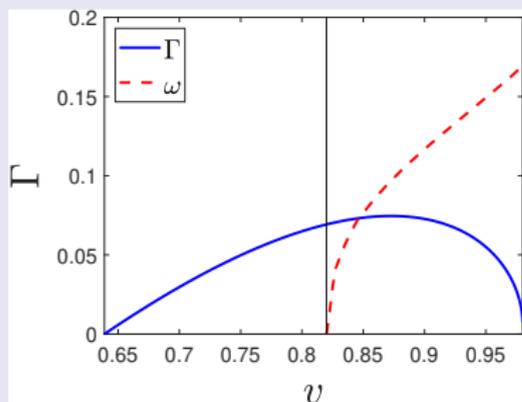

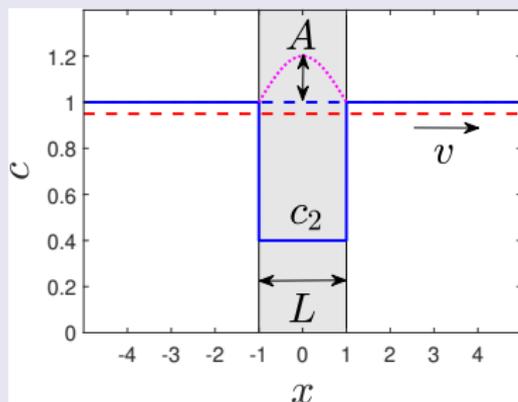

$$\Psi_0(x, t) = \Psi_0(x, \phi_0 + \omega t), \quad \Psi_0(x, \phi + 2\pi) = \Psi_0(x, \phi)$$

- Why not leveraging the quantum nature of Hawking radiation?
- BHL=DPA=Unstable pendulum:
 - Large initial amplitude \longleftrightarrow Classical (coherent) trajectory \rightarrow Late well-defined trajectory
 - Unstable position \longleftrightarrow Amplification of vacuum fluctuations through squeezing \rightarrow Superposition of eventual oscillations

Flat-profile BHL

- $t < 0$: Homogeneous subsonic condensate $\Psi_0(x) = e^{ivx}$
- $t \geq 0$: Inhomogeneous quench $g(x) + V(x) = 1 \rightarrow$ Finite size supersonic region \rightarrow BHL
 - Condensate does NOT experience dynamics $\rightarrow \Psi_0$ remains stationary
 - Quantum fluctuations DO experience dynamics \rightarrow Lasing amplification
- Short cavity containing only one degenerate lasing mode ($\Omega = i\Gamma$)
- Initial quantum state: $T = 0$ quasiparticle vacuum
- Small bump of amplitude A is added within the lasing region \rightarrow Coherent amplitude \rightarrow Small pendulum kick

Numerical results: Density & ETCF

- Truncated Wigner computation ($v = 0.95$, $c_2 = 0.4$, $L = 2$)
 - Ensemble-averaged density: $n(x, t) \equiv \langle \hat{n}(x, t) \rangle = \langle \hat{\Psi}^\dagger(x, t) \hat{\Psi}(x, t) \rangle$
 - Out-of-time density-density correlation function (OTCF):

$$g^{(2)}(x, x', t, t') \equiv \langle \hat{n}(x', t') \hat{n}(x, t) \rangle - n(x', t') n(x, t).$$

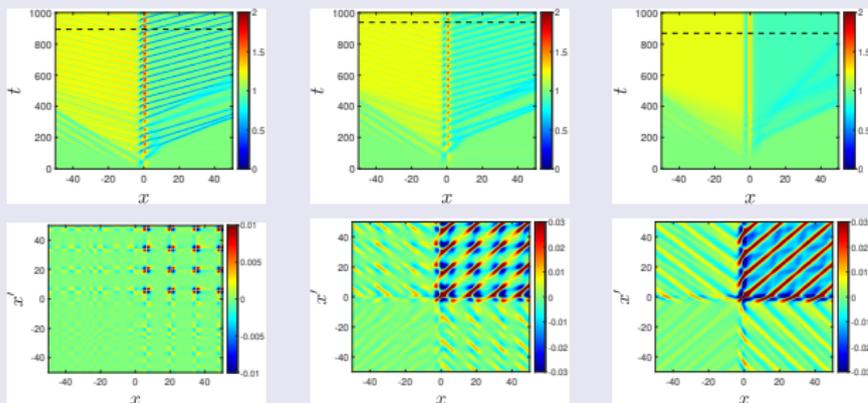

Figure: Classical-to-Quantum. Left to right: $A = 0.05, 0.005, 0$.
Upper row: $n(x, t)$. Lower row: ETCF $g^{(2)}(x, x', t) \equiv g^{(2)}(x, x', t, t)$.

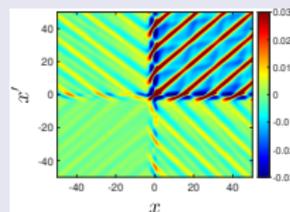

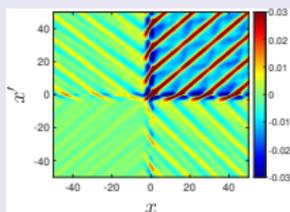

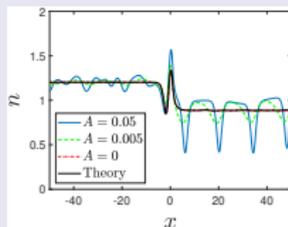

Numerical results: Density & ETCF

- Theoretical HTC prediction: Averages over different time-shifts $t_0 \in [0, T) \rightarrow$ Time-independent expectation values
 - Ensemble-averaged density: $n(x, t) = n_{\text{HTC}}(x)$

$$n_{\text{HTC}}(x) = \frac{1}{T} \int_0^T dt_0 n_0(x, t_0),$$

- ETCF: $g^{(2)}(x, x', t) = g_{\text{HTC}}^{(2)}(x, x', \tau = 0)$

$$g_{\text{HTC}}^{(2)}(x, x', \tau) = \frac{1}{T} \int_0^T dt_0 n_0(x, t_0 + \tau) n_0(x', t_0) - n_{\text{HTC}}(x) n_{\text{HTC}}(x')$$

Numerical results: OTCF

- Periodicity manifested in off-diagonal OTCF:

$$g^{(2)}(x, x', \tau; t) = g^{(2)}(x, x', t, t + \tau)$$

- HTC: $g^{(2)}(x, x', \tau; t) = g_{\text{HTC}}^{(2)}(x, x', \tau) = g_{\text{HTC}}^{(2)}(x, x', \tau + T)$
- Figure of merit: Normalized peak of Downstream-Upstream ($x > 0, x' < 0$) Fourier transform $\mathcal{G}^{(2)}(t, t')$
- $\mathcal{G}^{(2)}(t, t')$ becomes function only of $\tau = t' - t$

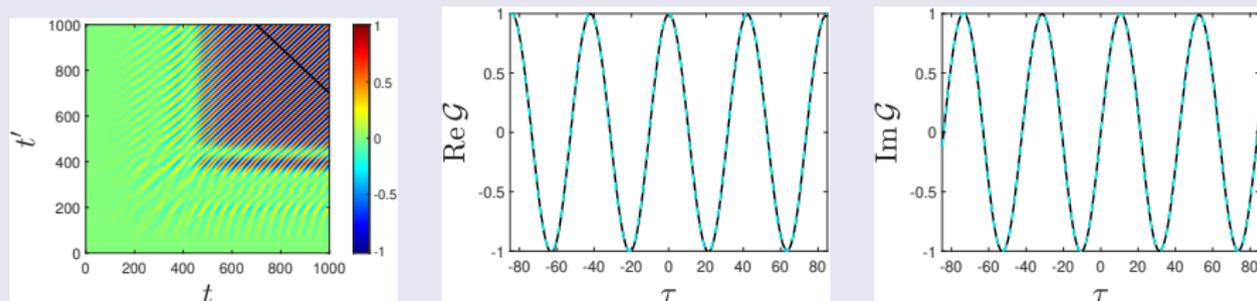

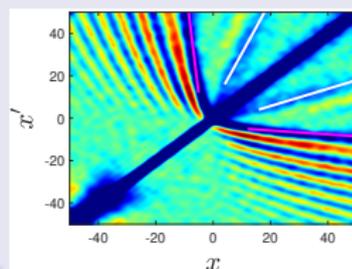

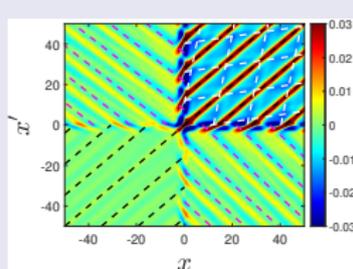

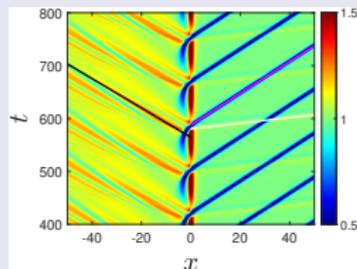

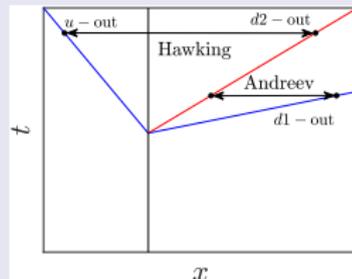

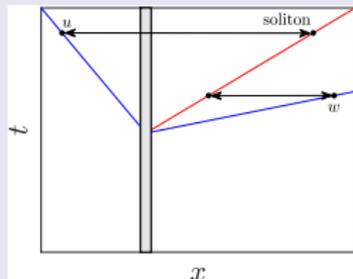

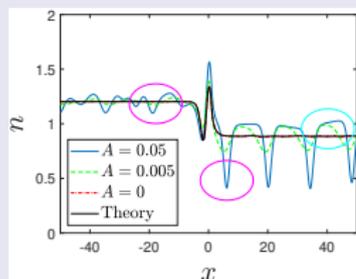

Figure: Left: $\text{Re } \mathcal{G}(t, t')$. Center: $\text{Re } \mathcal{G}(t, t')$ along black line. Right: $\text{Im } \mathcal{G}(t, t')$ along black line. Dashed cyan: Theory $\mathcal{G}_{\text{HTC}}(\tau) = e^{i\omega\tau}$.

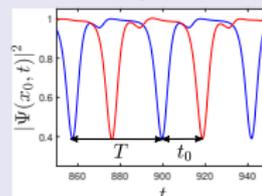

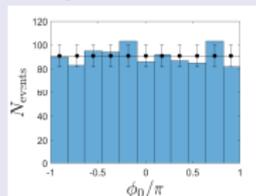

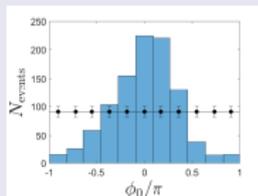

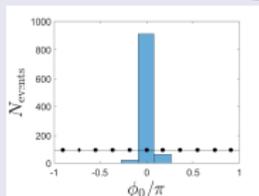

Nonlinear Andreev-Hawking effect

- Spatial correlation patterns arise from correlated quantum emission:
 - Downstream soliton (d2)
 - Upstream wave (u)
 - Downstream wave (d1)
- Nonlinear periodic analogue of Andreev-Hawking effect
- Time-periodicity + Traveling features = Space-periodicity

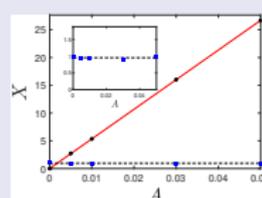

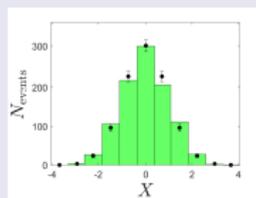

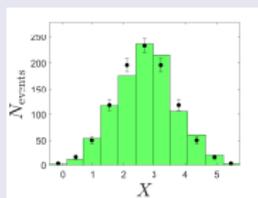

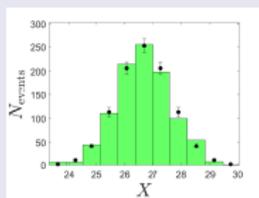

Histogram

- Late-time histogram of CES oscillation phase-shift $\phi_0 = -\omega t_0$:

- Simple model: Final CES state determined by initial lasing distribution

$$W_0(X) = \frac{1}{\sqrt{2\pi\Delta X_Q^2}} e^{-\frac{(X-X_C)^2}{2\Delta X_Q^2}}$$

- $X_C \sim A = \text{Mean} = \text{Classical component} \rightarrow \text{Mean-field trajectory}$
- $\Delta X_Q = \text{Width} = \text{Quantum fluctuations}$
- Crystallization \rightarrow Random oscillation phase-shifts $\rightarrow \Delta X_Q \gtrsim X_C$

DPA time operator

- Time evolution $U(t) = e^{-i\hat{K}t}$:

$$U(t) |X\rangle = e^{\frac{\Gamma t}{2}} |Xe^{\Gamma t}\rangle, \hat{X}(t) = U^\dagger(t)\hat{X}U(t) = e^{\Gamma t}\hat{X}$$

- Hamiltonian not bounded \rightarrow DPA time operator:

$$\hat{t} \equiv -\frac{1}{\Gamma} \ln \left| \frac{\hat{X}}{X_R} \right| \implies [\hat{t}, \hat{K}] = -i$$

- Continuous degenerate spectrum with two branches:

$$|t\rangle_\pm \equiv \sqrt{\left| \frac{dX_\pm}{dt} \right|} |X_\pm(t)\rangle, X_\pm(t) = \pm |X_R| e^{-\Gamma t}$$

$$\sum_{a=\pm} \int_{-\infty}^{\infty} dt |t\rangle_a \langle t| = \int_0^{\infty} dX |X\rangle \langle X| + \int_{-\infty}^0 dX |X\rangle \langle X| = 1$$

$${}_\pm \langle t|t'\rangle_\pm = \delta(t-t'), {}_\pm \langle t|t'\rangle_\mp = 0$$

- Physics: Time-shift with respect to certain reference amplitudes $\pm |X_R\rangle$. Different X_R , different time origin.

DPA time operator

- Whole spectrum generated through time translations:

$$|t\rangle_{\pm} = U(-t) |0\rangle_{\pm}$$

- Dynamics only needs to be computed for the two time origins $|t=0\rangle_{\pm}$ (i.e., reference lasing amplitudes $|X = \pm X_R\rangle$).
- Any state is a quantum superposition of different time realizations:

$$|\Psi\rangle = \sum_{a=\pm} \int_{-\infty}^{\infty} dt \Psi_a(t) |t\rangle_a = \sum_{a=\pm} \int_{-\infty}^{\infty} dt \Psi_a(t) U(-t) |0\rangle_a$$

- Time evolution simply shifts temporal wavefunction:

$$U(t) |\Psi\rangle = \sum_{a=\pm} \int_{-\infty}^{\infty} dt' \Psi_a(t') |t' - t\rangle_a = \sum_{a=\pm} \int_{-\infty}^{\infty} dt' \Psi_a(t' + t) |t'\rangle_a$$

- \hat{K} acts as $i\partial_t$ in temporal representation:

$$\hat{K} |\Psi\rangle = \sum_{a=\pm} \int_{-\infty}^{\infty} dt [i\partial_t \Psi_a(t)] |t\rangle_a.$$

Time operators

- Physics: Each $X = X_C e^{-\Gamma t_0}$ leads to different trajectory time-shifted t_0 with respect to mean-field

$$t_0 = -\frac{1}{\Gamma} \ln \frac{X}{X_C} \rightarrow \phi_0(X) = -\omega t_0$$

- Late ϕ_0 distribution determined by initial lasing distribution:

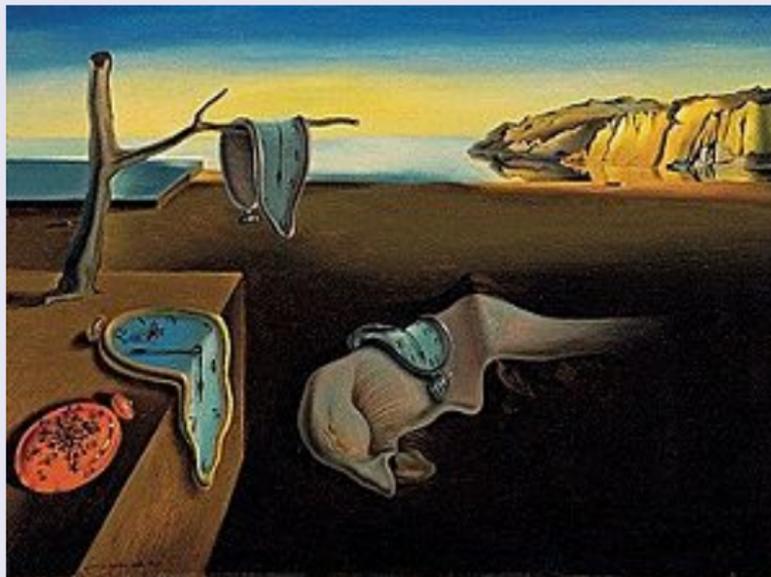

$$W(\phi_0) = \left| \frac{dX}{d\phi_0} \right| W_0(X)$$

- But t_0 is also the time amplitude of DPA time operator with $X_R = X_C$
→ Connection between initial (DPA) and final (CES) time operators!

***Disclaimer: Simplified (albeit illustrative) picture.*

Temporal Floquet-Goldstone mode

- BdG expansion for Floquet states:

$$\begin{aligned}\hat{\Phi}(\mathbf{x}, t) &= [\hat{X}^\alpha + \partial_A \lambda_B \hat{P}^B t] z_\alpha(\mathbf{x}, t) + \hat{P}^A z_A(\mathbf{x}, t) \\ &+ \sum_n \hat{\gamma}_n z_n(\mathbf{x}, t) e^{-i\varepsilon_n t} + \hat{\gamma}_n^\dagger \bar{z}_n(\mathbf{x}, t) e^{i\varepsilon_n t}\end{aligned}$$

- Spontaneous Floquet states: Genuine temporal Floquet-Goldstone mode z_ϕ arising from phase translations.
- Actual temporal Goldstone mode $z_t = \omega z_\phi$ whose conjugate are energy fluctuations:

$$\hat{X}^t = \hat{X}^\phi / \omega, \quad \delta \hat{K} = \omega \hat{P}^F \implies [\hat{X}^t, \delta \hat{K}] = i$$

- $\hat{t}_0 \equiv -\hat{X}^t$: Time operator describing quantum fluctuations of mean-field time origin $t_0 = -\phi_0/\omega$

Time operator

- Why there is no time operator $[\hat{T}, \hat{H}] = -i$? Pauli no-go theorem:

$$e^{-i\hat{T}E_0} \hat{H} e^{i\hat{T}E_0} = \hat{H} - E_0$$

- HORROR: Energy is bounded!
- Same for particle number/phase $[\hat{N}, \hat{\theta}] = i$:

$$e^{-i\hat{\theta}N_0} \hat{N} e^{i\hat{\theta}N_0} = \hat{N} - N_0$$

- HORROR: Particle number is non-negative and discrete!
- However, one can define phase fluctuations for large $N \rightarrow$ One can define time fluctuations for large E
- Spontaneous Floquet states must be highly-excited states! \rightarrow *Tangible* realization of time operator
